## 1 The Infinite Relational Model

What happens when you want to cluster your data, but the number of clusters is unknown? While some approaches involve fitting several models with a varying number of clusters to your data and comparing model fit statistics, the Bayesian approach is to specify a model which is allowed to dynamically grow the number of clusters as the complexity of the data warrants.

The **Infinite Relational Model** is the prototypical example of such a model.

Kemp et al. (2006). Learning Systems of Concepts with an Infinite Relational Model<sup>1</sup>

For this last project, a simple version of Charles Kemp's Infinite Relational Model (IRM) was coded in `irm.R` to co-cluster rows and columns of a simple 2-dimensional binary relation.

### 1.1 Demo

```
source('irm.R')
```

#### 1.1.1 Sanity check

As a sanity check, the toy matrix from the original paper is used:

```
R = rbind(
  c(0, 0, 1, 0, 1, 0, 0, 1, 0),
  c(0, 0, 0, 0, 0, 0, 1, 0, 1),
  c(0, 0, 1, 0, 0, 0, 1, 0, 1),
  c(0, 1, 1, 0, 0, 0, 0, 1, 1),
  c(0, 0, 0, 0, 0, 0, 1, 0, 1),
  c(0, 1, 1, 0, 1, 0, 0, 1, 0),
  c(1, 0, 0, 0, 0, 1, 0, 0, 0),
  c(0, 0, 0, 0, 0, 1, 1, 0, 1),
  c(1, 0, 0, 1, 0, 1, 0, 0, 0)
)
plot.R(R)
```

---

<sup>1</sup><http://web.mit.edu/cocosci/Papers/Kemp-et-al-AAAI06.pdf>

```
Z = irm(R, sweeps = 1000)
top.n(Z)
#> 122121323 122321424 122121324 122123424 122221323 123131434 122121343 122323424
#>      838      54      50      18      6      5      4      3
#> 122231232 123121425
#>      2      2
plot.R(R, mode.irm(Z))
```

This successfully finds the clusters of rows and columns that correspond to the original paper.
